

Machine Learning Lab 1

Junming Zhang 29299527 jz1g17@ecs.soton.ac.uk

Problem 1

Answer:

```
labone.m  x labone_2.m  x labone_3.m  x labtwo.m  x labtwo_2.m  x
1 -      x = rand(1000,1); % generate 1000 random numbers within 0 and 1
2 -      hist(x,40); % generate the frequency histogram for 40 ranges.
3 -      % the frequency histogram has equally 10 ranges and returns
4 -      % value of eachbin to nn and the center value of each bin to xx
5 -      [nn, xx] = hist(x);
6 -      bar(nn); % separate each bin.
```

```
labone.m  x labone_2.m  x labone_3.m  x labtwo.m  x labtwo_2.m  x
1 -      x = randn(1000,1); % generate 1000 random number drawn from a Gaussian
2 -      % distribution of mean=0 and variance=1.
```

Figure 1.1: result of labone.m

Figure 1.2: result of labone_2.m

It could find 'rand' command is uniform distribution and 'randn' is Gaussian distribution.

```
labone.m  x labone_2.m  x labone_3.m  x labtwo.m  x labtwo_2.m  x
1 -      N = 1000;
2 -      x1 = zeros(N,1); % create a 1000*1 matrix with 0
3 -      for n=1:N
4 -          % fill the matrix with two uniform random distribute arrays
5 -          x1(n,1) = sum(rand(12,1))-sum(rand(12,1));
6 -      end
7 -      hist(x1,100); % generate the frequency histogram for 100 ranges.
```

Figure 1.3: result of labone_3.m

It could find the result is similar to a Gaussian distribution. Due to the central limit theorem, in most situations, when independent random variables are added, their properly normalized sum tends toward a normal distribution.

Problem 2

```
labone.m x labone_2.m x labone_3.m x labtwo.m x labtwo_2.m x
1 - C=[2 1;1 2]; % covariance matrix
2 - X=randn(1000,2);% generate 1000*2 matrix with Gassian distribution
3 - A=chol(C); % A't&A = C
4 - Y=X*A;
5 - % mark Gaussian distribution with cyan potins
6 - % mark another Y with magenta x
7 - plot(X(:,1),X(:,2),'c.', Y(:,1),Y(:,2),'mx');
```

Figure 1.4: result of labtwo.m

This is using a linear transformation to generate the multivariate normal distribution. The n -dimensional random variable is normal distribution $N(u,B)$, suppose m dimensional random variable Y is the linear transformation of X , it means $Y=XC$, C is a $n*m$ matrix, therefore Y is m dimensional normal distribution $N(Uc,C'BC)$.

In this case, using Cholesky decompose to a covariance matrix and multiply a normal distributed matrix can obtain a linear correlated or negative correlated distribution which like figure 1.4.

```
labone.m x labone_2.m x labone_3.m x labtwo.m x labtwo_2.m x labtwo_2_2.m x
1 - C=[2 1;1 2];X=randn(1000,2);A=chol(C);Y=X*A;% correlated gaussian distribution
2 - N = 10;% test 10,100,1000,10000
3 - plotArray = zeros(N,1);thRange = linspace(0,2*pi,N);% setting coordinate system
4 - for n=1:N
5 -     theta = thRange(n);
6 -     u = [sin(theta); cos(theta)]
7 -     yp = Y*u;
8 -     var_empirical = var(yp)% matlab command
9 -     var_theoretical = u'*C*u %calculated
10 -    plotArray(n) = var_empirical - var_theoretical;%difference
11 - end
12 - plot(plotArray)
```

The curve will smooth with the increasing N from 10,100,1000,10000.

Figure 1.5: result of labtwo2_2.m

$$A - \lambda E = \begin{vmatrix} 2-\lambda & 1 \\ 1 & 2-\lambda \end{vmatrix} = (2-\lambda)^2 - 1 = 3 - 4\lambda + \lambda^2 = (\lambda - 1)(\lambda - 3)$$

Therefore, the eigenvalue of A is $\lambda_1 = 1$ and $\lambda_2 = 3$

When $\lambda_1 = 1$, $\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} * \begin{bmatrix} x_{11} \\ x_{12} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$, so $x_{11} = -x_{12}$ and the eigenvector is $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$

When $\lambda_2 = 3$, $\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} * \begin{bmatrix} x_{21} \\ x_{22} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$, so $x_{21} = x_{22}$ and the eigenvector is $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
